POPULATION TRANSFORMATIONS IN TRADITIONAL ECONOMIC REGIONS OF CENTRAL EUROPE. STRUCTURAL APPROACH

DOI: <http://dx.doi.org/10.2478/v10089-008-0013-7>

ABSTRACT. The subject of the Author's interest are traditional social-economic regions of Central Europe, i.e. the Katowice and Rybnik conurbations in Poland, and the Ostrava-Karvina agglomeration in the Czech Republic. Despite their similar origin – connected mainly with the exploitation of mineral resources, coal in particular – the directions of transformations in these regions have hitherto run differently in different time periods. The aim of this paper is an attempt to show differences in spatial development of population, mainly in relation: centre of a settlement system and its surroundings. The use of archival statistical materials made it possible to study these transformations from the beginning of the 19th century until now.

KEY WORDS: Katowice and Rybnik conurbation, Ostrava-Karvina agglomeration, population transformation, settlement, investigated areas.

POPULATION CHARACTERISTICS OF THE INVESTIGATED AREAS

In the Katowice conurbation the outer zone was identified with those towns which in the regional plan of 1953 were included in zone B; in the Rybnik conurbation towns which directly or indirectly bordered with Jastrzębie Zdrój, Rybnik, Wodzisław Śląski and Żory; in the Ostrava-Karvina agglomeration towns which were located beyond the core of Ostrava.

Katowice conurbation. Analysis of spatial distribution of social-demographic features has here a long-term tradition. This concerns especially urbanisation processes in the surroundings of towns in this conurbation. Different studies

concerning the structural approach to the problem were influenced on the one hand by the plan of deglomeration of its central part in the first post-war regional plan (similar activities in the Ostrava agglomeration – Havířov), and on the other hand by the occurrence and development of new economic areas beyond the centre. This approach was applied by such authors as Berezowski (1980), Grabania (1964), Kłosowski, Runge (1999), Krakowska (1983), Litewka (1971, 1979), Rajman (1969, 1977, 1997), Runge (1993, 1999), Runge, Zadrożny (1987). Especially the work by Kłosowski and Runge (1999) takes up the problems of consistency between the subsequent administration divisions of Katowice province and development of territorial social-demographic differentiations. A characteristic feature in this area was temporal-spatial changeability in population processes and structures, which was mainly a derivative of over-local economic investments.

Rybnik conurbation. Despite an eventful social-economic development of the Rybnik conurbation, research output on the post-war origin and development of this second in size settlement system is surprisingly inconspicuous (Dziadek, 1987; Runge, 1992). The processes of changes in this area were usually perceived as a part of all-Polish processes, emphasizing the main role of towns themselves in population concentration. The case of Jastrzębie Zdrój is a good example – the town with a health-resort function populated by several thousand inhabitants in the 1950s changed at the end of the 1970s and beginning of the 1980s into a mining town with an over 100 thousand population. This resulted for instance in intensive labour resource drainage of people living in surrounding towns and villages as well as those living in Podbeskidzie, the central part of Katowice (Silesia) province, and even from the former Częstochowa province (Runge, 1992). Paradoxically, the results of this process have not been described in scientific literature, which should be connected – similarly to the Katowice Steelworks case – with political reasons.

Ostrava-Karvina agglomeration. Still developing after 1945 the Ostrava agglomeration was luckier in recording the process of transformations. The most important are probably the works by Prokop (1968, 1980, 1993, 2003). The dynamics of population changes in the main towns of Moravian-Silesian country after 1950 was significantly differentiated. The decision on the location of a new town on a “coarse root” of Havířov, as well as intensive development of coal mining in the area of Karvina means that by the 1970s, the population centre of gravity was shifted towards the south-east (Havířov, Frydek-Mistek). In the period 1971–1991, Frydek-Mistek was a leader in population development, with the clearly weakening position of other urban centres. The reason is probably the fact that Frydek-Mistek was the second town with a residential function after Havířov located in close neighbourhood to Ostrava. The attractiveness of the town, good transport connections with the regional capital and also the close distance to the

Moravian-Silesian Beskidy Mountains as a recreational area for the inhabitants of the Ostrava-Karvina agglomeration meant that suburbanisation processes were clearly directed to the south. After 1990, in nearly all urban centres the regress in population is visible. The exception is Petřvald and Rychvald, small towns connected with coal mining and located on the eastern side of the Ostrava sphere of influence.

LONG-TERM TRENDS OF POPULATION CHANGES

A systematic reflection of the structural approach to determine directions of transformations of the settlement systems studied and their spheres of influence are long-term changes in the population of individual towns included in these systems. Despite the fact that in the case of the territory of Poland, there are suitable records from as early as 1810 (Jelonek, 1956), many urban centres do not have reliable statistical data for the beginning of the 19th century. Therefore in this studies the Author applied data from Gawryszewski (2005) and from the Statistical Office in Ostrava (from 1869). Table 1 contains towns of the three settlement systems studied, leading in population structure in 16 comparable time intervals.

Table 1. Towns dominating in population structure in traditional regions in Central Europe (period 1869–2005)

The Czech data show that since the 1860s, the leading role of the central town, i.e. Ostrava, in population distribution is clearly visible. On the other hand, Opava, the second large town in this area, does not differ much from Ostrava (only 6% less), but in the successive years, the predominance of Ostrava over other towns grew, reaching at the beginning of the 20th century 36.6% of the total population of the present territory of Moravian-Silesian country.

In the case of the towns of the Katowice conurbation, until the 1860s, the predominant role in population concentration was held by Gliwice (1810), Będzin (1825), Gliwice and Bytom (1843/1857), Chorzów, Zabrze, Bytom (1869, 1880, 1890, 1897). The process of evolution of the standing of towns in the Katowice conurbation and its reasons are discussed by Gwosdz (2004).

The third settlement system studied is the Rybnik conurbation. Until the 1890s, the leading but decreasing position in population concentration was held by Żory. In 1890 Rybnik (population –5.2 thousand) gained superiority over Żory (4.4 thousand).

At the beginning of the 20th century, the situation in population concentration of the three settlement systems studied was strongly differentiated. The agglomeration pattern, showing the largest population concentration in the centre and decreasing values towards the peripheries was typical only for the Ostrava region. In 1990, Ostrava was populated by 36.6% of the inhabitants of this region, with a large proportion of towns located almost concentrically in relation to Ostrava. In the Katowice conurbation as much as 65% of demographic potential was concentrated in the western and central part (Bytom, Chorzów, Gliwice, Katowice, Zabrze). Katowice itself only slightly predominated over other towns in population concentration, which resulted in the fact that in 1910 Zabrze overtook Katowice in population number. In the just industrialising Rybnik conurbation, only two towns showed predominating role in population concentration – Rybnik and Żory – creating a clear bipolar settlement system.

Until 1939, trends in population changes were as follow:

- In the Katowice conurbation there was an increase in the number of towns with large percentage of population. In this group towns from the former Russian sector appear such as Będzin, Dąbrowa Górnica, Sosnowiec. This way a clear shift of the centre of gravity in the conurbation population occurs from the central-western part to the central-eastern part of the region. Intensification of this process appeared after 1945.
- In the Rybnik conurbation the increasing population supremacy of Rybnik over surrounding towns meant that this area in the period 1921–1939 may be considered as an agglomeration.
- In the Ostrava agglomeration a relative stabilisation of the dominating role of Ostrava as a centre of the demographic settlement system occurs. Population hierarchy of other towns is practically stable. The second position – since the beginning of this region development – is held by Opava.

The post-war period brings many changes, which are best visible in the territorially and demographically smallest area studied. As a result of hard coal mining development in the newly established Rybnik Coal Area, possibilities for rapid population increase were gained by: Czerwionka-Leszczyny, Jastrzębie Zdrój, Knurów and Wodzisław Śląski. From the position of over 70% population concentration (in 1939) Rybnik decreases its predominance to the level of 30% in 2005.

In the second position of the scale of qualitative changes was the Ostrava agglomeration. The development of Havířov as a satellite town caused the shift

of the population centre of gravity towards the south-west. The leading hitherto towns such as Ostrava, Opava, Nový Jičín, Karviná, are replaced by Ostrava, Havířov and Karviná, which gave the reason to change the name of this area – from the Ostrava agglomeration to the Ostrava-Karvina agglomeration.

In the Katowice agglomeration, a relative stabilisation of population level of Katowice was already seen in the inter-war period, oscillating between 13 and 15% of the total population in towns of this region. The consolidation of the process of shifting the population centre of gravity towards the towns of Zagłębie Dąbrowskie occurred in the late 1970s, when housing development was realised with vehemence for the labour force of Katowice Steelworks. Since 1978, Sosnowiec and Dąbrowa Górnica have played a role of leading urban centres in this area.

It is very interesting to compare the population structure of dominating towns in the 21st century (2002, 2005). Urbanisation processes are mainly visible in the Ostrava-Karvina agglomeration, where the role of Ostrava decreases, whereas the increase occurs in such towns as Orlová, Nový Jičín, Český Těšín, Krnov, Kopřivnice, Bohumin, or Bruntal. These are mainly towns of a distant part of the influence sphere of the agglomeration, located partly near state boundaries of these areas. Therefore, the suburbanisation process among all the settlement systems studied is best advanced in the Ostrava-Karvina agglomeration.

INNER-URBAN CHANGES OF POPULATION

Similarly to the changeable role of individual urban centres in population concentration, there were also differences in this respect on the levels of town districts of the three settlement systems studied. Unfortunately, the Author had suitable data only for Ostrava for the period 1869–2001. It is assumed that changes in functional structure were accompanied by essential changes in population concentration. Table 2 shows information about the population of individual districts of Ostrava from the second part of the 19th century to the beginning of the 21st century. In 1869 the leading position was held by Slezska Ostrava. Together with the industrial development the role of Moravská Ostrava and Privoz increased. In the 1950s and 1960s, a socialistic housing district Poruba was built which concentrated most of the population until 1980. After 1990, this role was taken by Ostrava Jih (Ostrava South).

CONCLUSIONS

The presented in this work trends of population transformations in three traditional economic regions of Central Europe lead to the following conclusions:

- *firstly* – there is a clear disproportion in the range of investigations of the area studied, taking into account three applied approaches. Relatively, the largest amount of research work concerns the structural approach, slightly less – the hierarchical-functional approach, and the least amount of research concerns the network approach;
- *secondly* – irrespective of similar or close origin, the process of social-economic changes of the regions studied occurred differently, which is reflected in the advancement of urbanisation process phases;
- *thirdly* – both the spatial range and character of transformations of the constituents in the system centre – peripheries show clear differentiations on both Czech and Polish sides;
- *fourthly* – it is therefore difficult to assume that a traditional region in its historical and geographical transformations shows a model homogeneity.
